Life Satisfaction in Western Europe and the Gradual Vanishing of the U-shape in Age
David G. Blanchflower and Alex Bryson
NBER Working Paper No. 33950
June 2025
JEL No. I31

ABSTRACT

Using Eurobarometer data for 21 Western European countries since 1973 we show the U-shape in life satisfaction by age, present for so long, has now vanished. In 13 northern European countries - Belgium, Denmark, Finland, Germany, Iceland, Ireland, Luxembourg, the Netherlands, Norway, Sweden, Switzerland, Turkey and the UK - the U-shape has been replaced by life satisfaction rising in age. We confirm these findings with evidence from the European Social Surveys, the Global Flourishing Survey and Global Minds. Evidence of change in the U-shape is mixed for Austria and France. In six southern European countries – Cyprus, Greece, Italy, Malta, Spain and Portugal - the U-shape was replaced by life satisfaction declining in age. In these southern European countries, life satisfaction of the young has been rising since around 2015. A contributory factor is the rapid decline in youth unemployment from its 2015 peak.

1. Introduction

In the decades up to the outbreak of the COVID pandemic in 2020 there were over 600 published papers showing a global mid-life morbidity crisis. Life satisfaction and happiness were U-shaped in age (Blanchflower, Graham and Piper, 2023, Blanchflower, 2021) whilst negative affect, variously defined, was hump-shaped in age peaking in mid-life (Blanchflower, 2020). This hump-shape was also apparent in ‘deaths of despair’ from drug overdoses, suicide and alcohol poisonings (Case and Deaton, 2020).

However, evidence began to mount indicating that the mental health of the young had begun to decline – as early as about 2013. This was first reported in a series of papers by Jean Twenge (Twenge, 2020, 2023; Twenge et al., 2018, Udupa et al 2023) but has now been observed across 167 countries (Blanchflower, 2025) and in a series of studies for separate countries.¹ This shift has been accompanied by behavioral change among the young, most notably rising suicide rates in the United States (Ehlman et al, 2022, Garnett and Curtin, 2023; Marcotte and Hansen, 2024) and rising unsuccessful suicide attempts (Yard et al., 2022).²

This deterioration in the mental health of the young has continued during COVID. This is apparent in the Netherlands, for example, where reported poor mental health and visits to the General Practitioner for mental health reasons among 15–24-year-olds have risen markedly since 2019.³ Similar trends are apparent elsewhere. For example, in Sweden self-reported worry or anxiety has increased in the Swedish population and the prevalence is especially high among young women, i.e., those aged 16–29 years. Severe worry or anxiety was reported by 23 percent of the young women 2024. In 2011, the corresponding proportion was 9 percent. For young men, there has been a similar increase, from 5 percent 2011 to 10 percent 2024.⁴

Blanchflower et al. (2024) were the first to point out that this deterioration in the mental health of the young had changed the age-pattern in subjective illbeing such that, in both the United States and the United Kingdom, the hump-shape in illbeing had been replaced by a linear trend, with illbeing falling in age. The disappearance of hump-shape in illbeing is apparent elsewhere around the world too – in Asia and the Middle East (Blanchflower and Bryson, 2025) and in Latin America (Blanchflower and Bryson, 2024).

Debate as to what lies behind these changes is on-going. Central to the debate have been concerns regarding the role of social media (Twenge, 2023; Haidt, 2024) with commentators pointing to various mechanisms at play including social comparisons, impacts on brain function, displacement effects on other activities, information overload and cyberbullying (Human Development Report

¹ These studies include recent evidence for Australia (Botha et al, 2023 and Leigh and Robson, 2025), Canada (Garriguet, 2021), Norway (Krokstad et al, 2022), Iceland (Thorisdottir et al, 2021), the Netherlands¹, and the United States (Daly, 2022; Haidt, 2024).

² Recent evidence from the European Commission shows rising suicide rates of youngsters ages 15-19 in twelve EU countries between 2011 and 2022 but falls elsewhere

⁴ Mental Health, Public Health Agency of Sweden, <https://www.folkhalsomyndigheten.se/the-public-health-agency-of-sweden/living-conditions-and-lifestyle/mental-health/>

Office et al., 2025). Although contested, there is growing evidence that interactions with social media may have a causal impact on young people's mental health.⁵ It appears that extended use of smartphones is particularly problematic. For example, Liu et al (2022) find that more time spent on social media, "is associated with a higher risk of depression in adolescence in a linear dose–response manner, especially for teenage girls."

Little prior work has examined the extent to which the previously well-documented life satisfaction and happiness U-shapes in age have remained intact. The studies that have been undertaken are not consistent.

Twenge and Blanchflower (2025) document changes in youth well-being, primarily life satisfaction, in six English speaking countries – Australia, Canada, Ireland, New Zealand, the United Kingdom and the United States. Broadly speaking, they find evidence across, all of these, English-speaking countries that happiness and life satisfaction have been rising in age since 2020. In several of these surveys they also found that illbeing declines in age. The U-shape in wellbeing by age, they found, that used to exist in these countries is now gone, replaced by a crisis in wellbeing among the young. However, Marquez et al. (2024) come to very different conclusions analysing Gallup World Poll data for the period since 2005. They maintain that "globally, adolescents aged 15-24 report higher life satisfaction than adults aged 25 or above" Marquez et al (2024: 91), although they go on to say that "the gap between those aged 15-24 and those 25 and older is contracting in Western Europe".

More broadly, age patterns in positive affect since 2020 differ across surveys. Where surveys are conducted with an interviewer (either face-to-face or online) – as in the case of Gallup World Poll data – the young score more highly than when the survey is conducted on-line, as in the case of the Global Minds data (<https://sapienlabs.org/>). Blanchflower and Bryson (2025) examined the issue of survey mode further, confirming that young people's responses on wellbeing appeared more sensitive to the way the survey was conducted than in the case of older people. This raises important questions about one's ability to measure changes in age patterns in wellbeing over time, not least because push-to-web is an important development in survey technology in recent years.

In this paper we contribute to the literature by focusing on changes in life satisfaction in 21 Western European countries since 1973. We show the U-shape in life satisfaction by age has now vanished, but in perhaps a surprising fashion. In 13 northern European countries - Belgium, Denmark, Finland, Germany, Iceland, Ireland, Luxembourg, the Netherlands, Norway, Sweden, Switzerland, Turkey and the UK - the U-shape has been replaced by life satisfaction rising in age. (Evidence of change in the U-shape is mixed for Austria and France). But in six southern European countries – Cyprus, Greece, Italy, Malta, Spain and Portugal - the U-shape was replaced by life satisfaction declining in age. In these southern European countries, life satisfaction of the young has been rising since around 2015. A contributory factor is the rapid decline in youth unemployment from its 2015 peak.

⁵ Pugno (2025) reviews a set of papers that have used natural experiments suggesting a causal connection between the arrival of fast broadband and deteriorating well-being of the young. Evidence is provided in Braghieri, Levy and Makarin (2022), McDool, Powell, Roberts and Taylor (2020), Golin (2022), Donati, Durance, Sobbrío and Zejcirovic (2024), Arenas-Arroyo et al (2022), Kyung, Lim and Lee, (2021).

The remainder of the paper is structured as follows. Section Two describes our data and estimation. In Section Three we present our findings. Section Four concludes with a discussion of the implications.

2. Data and Estimation

We describe the seven data sets we analyze in this paper in turn, beginning with the Eurobarometer which is our primary focus. We run simple Ordinary Least Squares (OLS) regressions on life satisfaction, variously defined and generally controlling for gender and year dummies and, in pooled regressions, for country dummies.

We restrict samples to those age under 70, but in the case of Global Minds we can only use under 75 as the age data are only reported in bands. We use this restriction because Hudomiet et al (2023) have documented in the United States using data from the Longitudinal Health and Retirement Survey a mortality selection bias at around age 70 as happy people live longer.⁶ It is unclear the extent to which this mortality selection bias operates in Europe.

We consider the relationship between life satisfaction and age in a variety of ways across 21 European countries:

- a) Single year of age, between ages 18 and 70.
- b) Age bands 15/18-24, 25-34, 35-44, 45-54, 55-64 and 65-69/74.
- c) Age and its square and solve for a minimum by differentiation with respect to age, so dividing the age coefficient by (2*age squared coefficient) and then multiplying by -1.
- d) An age 18-24 or 15-24 dummy.
- e) A continuous age variable.

In general, though they tend to tell a broadly similar story.

2.1: Eurobarometer surveys, 1973-2024

Our main data source is the EU Commission's Eurobarometer Survey (henceforth EB) series which has been conducted since 1972 by the EU Commission. The various cross-sectional micro surveys, often including several each year, can be downloaded from the German data archive GESIS (<https://www.gesis.org/en/home>).⁷ A subset of these EB surveys include questions on well-being, with the proportion that do so rising over time. To our knowledge, this is the longest continuous well-being survey available.

The main question we focus on is this 4-step variable which appears in many, but not all, sweeps of the survey.

⁶ They argue that “both differential mortality and differential non-response bias the cross-sectional age profile upward: individuals with higher life satisfaction and in better health tend to live longer, and, among survivors, individuals with higher life satisfaction are more likely to remain in the survey, masking the decline in life satisfaction experienced by individuals as they age. We conclude that the optimistic view about increasing life satisfaction at older ages based on cross-sectional data is not warranted.”

⁷ <https://www.gesis.org/en/eurobarometer-data-service/data-and-documentation/standard-special-eb/study-overview>

Q1. On the whole, are you very satisfied (=4), fairly satisfied (=3), not very satisfied (=2) or not at all satisfied (=1) with your daily life?

We pool the 176 surveys containing the life satisfaction question for the period 1973-2024 excluding 1974 which has no data availability.⁸⁹ In total we have 2,421,597 observations. The panel of countries is unbalanced across the 51 years of data. Details by year by country are reported in **Appendix One**. The survey started with nine participating countries – Belgium, Denmark, France, Germany, Ireland, Italy, Luxembourg, Netherlands and the United Kingdom have responses in all these years. As countries join the EU, they participate in the Eurobarometers and sometimes prior to their joining. The years available by country are as follows - Greece (1981-2024), Spain and (1985-2024), Portugal, Finland (+1992) Sweden and Austria (1995-2024), Cyprus and Malta (2005-2024), Turkey (2004-2025) with 7 years of observations and Iceland and Switzerland 2021-2023. After Brexit the UK left the survey. Sample sizes are over 100,000 for fifteen countries.¹⁰

The EB surveys prior to 2020 used Computer Assisted Personal Interviewing (CAPI), an in-person or face-to-face research method in which interviewers use software on a computer or tablet to record interview responses. CAPI is an interviewer-administered mode, meaning that interviewers can clarify questions that may be unclear to respondents and ask follow-ups. In the years 2020-2023 both CAPI and online survey collection methods were used, known as Computer Assisted Web Interviewing (CAWI) which are surveys administered through a web browser or mobile application. Links for CAWI surveys can be sent through multiple methods, including email, mobile application notifications, online advertisements, and SMS messages. CAWI surveys are useful for gathering quick insights from large sample sizes as they do not require interviewers to be trained and can be distributed very widely, but they are limited to populations who have internet access and are comfortable using computers or internet-enabled phones or tablets.

Rickwood and Coleman-Rose (2023) have noted that there is evidence that people completing interviewer administered questionnaires are more likely to provide socially desirable responses than if they are self-administered. In the literature this is called social desirability response bias which

⁸ The earliest Eurobarometer with life satisfaction data is called the European Communities Study from September-October 1973 and is sometimes called Eurobarometer 0. <https://www.gesis.org/en/eurobarometer-data-service/data-and-documentation/standard-special-cb/study-overview/eurobarometer-ecs-1973-za-0628-sep-oct-1973>

⁹ The surveys we use are as follows - 0; 30; 40; 50; 60; 70; 80; 90; 10.0; 10.1; 11.0; 12.0; 13.0; 14.0; 15.0; 16.0; 17.0; 18.0; 19.0; 20.0; 21.0; 22.0; 23.0; 24.0; 25.0; 26.0; 27.0; 28.0; 28.1; 29.0; 30.0; 31.0; 31.1; 32.0; 33.0; 34.0; 34.2; 35.1; 36.0; 37.0; 37.1; 37.2; 38.0; 38.1; 39.0; 39.1; 40.0; 41.0; 41.1; 42.0; 43.0; 43.1; 43.2; 44.0; 44.1; 44.3; 44.4; 45.1; 46.0; 46.1; 47.0; 47.1; 47.2; 48.0; 49.0; 50.0; 50.1; 51.0; 51.1; 52.0; 52.1; 53.0; 54.0; 54.1; 54.2; 55.0; 55.1; 55.2; 56.0; 56.1; 56.2; 56.3; 57.0; 57.1; 57.2; 58.1; 60.1; 61.0; 62.0; 62.2; 63.4; 64.2; 65.2; 66.1; 66.3; 67.2; 68.1; 69.2; 70.1; 71.1; 71.2; 71.3; 72.4; 73.4; 73.5; 74.2; 75.3; 75.4; 76.3; 77.3; 77.4; 78.1; 79.3; 79.4; 80.1; 80.2; 81.1; 81.2; 81.4; 81.5; 82.1; 82.2; 82.3; 82.4; 83.1; 83.2; 83.3; 83.4; 84.2; 84.3; 84.4; 85.1; 85.2; 85.3; 86.1; 86.2; 86.3; 87.1; 87.2; 87.3; 87.4; 88.1; 88.2; 88.3; 88.4; 89.1; 89.2; 89.3; 90.1; 90.2; 90.3; 90.4; 91.2; 91.3; 91.4; 91.5; 92.1; 92.2; 92.3; 92.4; 93.1; 93.2; 94.1; 94.3; 95.1; 95.2; 95.3; 96.1; 96.3; 97.3; 97.5; 98.2; 99.4; 100.2; 101.3 and 101.4

¹⁰ France=148,403; Belgium=148,768; Netherlands=147,360; Germany=225,666; Italy=151,508; Luxembourg=68,382; Denmark=146,616; Ireland=146,269; UK=178,946; Greece=134,724; Spain=127,211; Portugal=128,242; Finland=104,169; Sweden=104,837; Austria=102,482; Norway=11,001; Cyprus=43,984; Malta=43,507; Turkey=42,130; Iceland =6,217 and Switzerland=6,284.

is the tendency to underreport socially undesirable attitudes and behaviors and to over report more desirable attributes.¹¹

We explore survey mode effects below but find responses are not as sensitive to the method used compared with other surveys (Blanchflower, 2025 and Blanchflower and Bryson, 2025).

In addition to descriptive trends in mean life satisfaction, by age, we run ordinary least squares (OLS) estimates, focusing on differences across six age bands, where under-25 is the reference category. Pooled country equations incorporate gender and year dummies, as well as country dummies. We also run estimates for separate countries by grouped years and, in sensitivity analyses, replace the age dummies with alternative parameters capturing age.

2.2: The Remaining Surveys

The remaining analyses were undertaken with six different surveys.

We analyze responses in the **Gallup World Poll (GWP)** for the period 2018-2025 to the following question:

Q2. "Please imagine a ladder, with steps numbered from 0 at the bottom to 10 at the top. The top of the ladder represents the best possible life for you and the bottom of the ladder represents the worst possible life for you. On which step of the ladder would you say you personally feel you stand at this time?"

This is known as Cantril's Ladder. We run 21 separate country OLS estimates for individuals aged 18 to 70, focusing on responses in six age categories with age under-25 the reference category, controlling for gender and year dummies.

For the **European Social Survey (ESS)**, we run separate life satisfaction equations for 17 countries, namely Austria, Belgium, Cyprus, Denmark, Finland, France, Germany, Greece, Ireland, Italy, Netherlands, Norway, Portugal, Spain, Sweden, Switzerland and the United Kingdom. Models are run for Sweeps 7 to 10 pooled (for the period 2014-2020) and separately for Sweep 11 conducted in 2023/24. We present coefficients for age and age squared in models that also contain a gender dummy. The dependent variable, which is estimated with an OLS, is an 11-step life satisfaction variable as follows:

Q3. All things considered, how satisfied are you with your life as a whole nowadays? Please answer using this card, where 0 means extremely dissatisfied and 10 means extremely satisfied.

We run OLS estimates using the **Global Flourishing Study (GFS), 2023/24** which contains data on Germany, Spain, Sweden, Turkey and the United Kingdom. The dependent variable is an 11-step life satisfaction question:

Q4. How satisfied are you with life as a whole these days? Coded 0-10.

¹¹ Exploiting random assignment to survey mode, Reisinger (2022) shows that the under-reporting of depression and over-reporting of happiness in surveys that do not permit anonymous reporting is causally linked to survey mode.

We run separate country regressions controlling for gender. Age is captured with six categorical variables with aged under-25 the reference category. In a second specification we capture age with age and age squared.

Using the web-based survey **Global Minds 2020-2024 (GM)** we run OLS equations for a 9-step life satisfaction question for six separate countries - Belgium, France, Ireland, Spain, Switzerland and the United Kingdom. In a recent subset of surveys, a 9-step life satisfaction question (Q6) has been asked in a subset of six European countries – Belgium, France, Ireland, Spain, Switzerland and the UK. We only have age in bands, and no continuous age variable is provided. There are only 407 observations in Switzerland but over 23,000 for the UK. The question is:

Q5. How satisfied are you with your life in general? 1 = not at all satisfied... 9 = extremely satisfied

Our estimates control for gender and year dummies.

To establish change in wellbeing among school-age children we rely on two surveys. The first is the OECD's **Programme for International Student Assessment (PISA)** conducted in 2015, 2018 and 2022 for high school students aged 15/16. In each of those three years young people were asked:

Q6. "The following question asks how satisfied you feel about your life, on a scale from "0" to "10". Zero means you feel 'not at all satisfied' and "10" means 'completely satisfied'. Overall, how satisfied are you with your life as a whole these days?"

We report the mean scores each year for 13 European countries – Austria, Finland, France, Germany, Greece, Iceland, Ireland, Netherlands, Portugal, Spain, Switzerland and the UK.

The second is the **Health Behaviour in School-aged Children (HBSC) Survey** conducted in 2017/2018 and 2020/21 among 15-year-olds. They are asked:

Q7. "Here is a picture of a ladder. The top of the ladder '10' is the best possible life for you, and the bottom '0' is the worst possible life for you. In general, where on the ladder do you feel you stand at the moment? Tick the box next to the number that best describes where you stand."

We report mean scores for each of 15 countries for each year.

Both the PISA and HBSC surveys are conducted in collaboration with the WHO Regional Office for Europe. Data are collected in the HBSC surveys from pupils in mainstream schools using a self-report questionnaire. Pupils complete the questionnaire in school as a whole school class, using either pencil and paper or an electronic survey mode. The PISA surveys also use self-completion surveys.

The mean scores from PISA and HBSC correspond to those in Marquez et al (2024). We confirmed their finding from the micro data.

Of note is that the GWP, ESS and GFS surveys are collected using interviewers and/or telephones. By contrast the PISA, HBSC and GM surveys are collected via the internet.

3. Results

3.1: Eurobarometers (EB), 1973-2024

Figure 1 plots the relationship between single year of age and life satisfaction for 2020-2024 for each of the 21 countries in Western Europe in the data. We obtain these estimates by regressing life satisfaction on single year of age dummies, gender and year, setting age 18 to zero. We extract the coefficients and add them to the constant and plot. We also report a best-fit linear trend line to the scatter plots.

We find the function slopes upwards in age in twelve countries - Belgium, Denmark, Finland, Iceland, Ireland, Luxembourg, the Netherlands, Norway, Sweden, Switzerland, Turkey and the United Kingdom – indicating that life satisfaction rises in age. We show that in further detail with different specifications and data sets below.

However, there are downward slopes in the remaining nine countries – Austria, Cyprus, France, Germany, Greece, Italy, Malta, Portugal, Spain. An obvious question here is what distinguishes the group of countries where life satisfaction is rising in age from those where it declines in age. We return to this below.

Tables 1 and 2 report the relationship between life satisfaction and age using the full time series from 1973, split into three time periods: 1973-2009; 2010-2019 and 2020-2024. In every case we report five age bands (with under-25s as an additional age band used as the reference category) and then separately a continuous age variable from a separate equation with gender and year controls.

Table 1 starts with data from 1973 (excluding 1974 for which we have no data) through 2009 using six ten-year age bands, using method b) above with the excluded category ages 15-24. As noted in the **Appendix** we have data on all these years for Belgium, Denmark, France, Germany, Ireland, Italy, Luxembourg, Netherlands and the UK, Greece joins in 1981, Spain and Portugal in 1985, Finland, Sweden and Austria in 1995 and Cyprus and Malta in 2004. Sample sizes vary from around 100000 to 9000, with ten countries with over 50000.

There is evidence of a U-shaped relationship between age and life satisfaction in every country except Luxembourg, with a minimum mostly in the age category 45-54. Four have minima in the 55-64 grouping (Greece, Spain, Norway and Portugal) with Turkey in the 35-44 group.

Table 2 runs the same analyses, but for the period 2010-2019. Here there are age minima in every country except Greece which showed a linear decline, with ten in the age 45-54 category. Both, **Tables 1 and 2** are consistent with the findings of widespread U-shapes with minima around age 50 (Blanchflower, 2021 and Blanchflower, Graham and Piper, 2023). In every country in both tables the function minimizes in middle-age.

But in **Table 3** the U-shape disappears. It uses data on individuals whose responses were obtained via CAPI for 2020-2024. Sample sizes range between 3000 and 12000. Overall, there are 231,608

observations on these 21 countries of which 150,714 or 65.1% are CAPI.¹² Focusing on the single age variable specification for simplicity there are *upward slopes* in seven: Denmark, Finland, Ireland, Luxembourg, the Netherlands, Sweden and the UK. There are downward slopes in eleven - Austria, Belgium, Cyprus, France, Germany, Greece, Italy, Malta, Portugal, Spain and Turkey.

Table 4 reports life satisfaction in Eurobarometer, also for 2020-2024 but this time for the online CAWI surveys. We see:

- 1) All of the seven countries with upward slopes using CAPI (Denmark, Finland, Ireland, Luxembourg, the Netherlands, Sweden and the UK) also have them with CAWI
- 2) Out of the eleven in CAPI with downward slopes, six also had downward slopes with CAWI. These are Cyprus, France, Greece, Italy, Portugal, and Spain.
- 3) Now Belgium, Germany, Norway, Switzerland and Iceland also had upward slopes.
- 4) Now the coefficients on age are insignificant in Austria, Malta and Turkey.

Table 5a explores other ways of examining the age pattern in life satisfaction during 2020-2024 using methods a)-e) described at the start of Section Two. It turns out the results are highly consistent whichever method is used, including the single year of age plots in **Figure 1**.

The first column reports results from regressions where age is specified as a continuous variable rather than the age bands. In Belgium, Denmark, Finland, Iceland, Ireland, Luxembourg, Netherlands, Norway, Sweden and Switzerland, but not Turkey, its coefficient is significantly positive.

Column 2 presents results, from regressions, where the continuous age variable is replaced by an age dummy where individuals aged 18-24 score '1'. It is significantly negative (lower happiness of the young) for Denmark, Iceland, Ireland, Netherlands, Norway, Sweden and the UK.

Columns 3 and 4 present estimates from a third model specification which contains both age (column 3) and age squared (column 4) terms as per the specification used in the prior literature. A significant U-shape is apparent where the age term is significantly positive, and the age squared term statistically negative ($T > 1.5$). There were no significant U-shapes in ten of the twelve countries that had upward lines in **Figure 1**. In the case of Ireland, the minimum was at age 24, while Turkey had a minimum at age 43.

Table 5b explores the time series changes by year since 2010. For simplicity we include the continuous age variable as in method e). We estimate separate equations by country for 2010-2017 pooled, and then every year from 2018. It is apparent that 2020 is the point at which the age coefficients start to change from negative to positive and especially so in the twelve countries referred to above which had positive trends in **Figure 1**. Sweden is notable for having positives in every case.

¹² By country the proportions CAPI are Austria 77%, Belgium 58%; France 77%; Germany 79%; Greece 75%, Ireland 77%; Italy 77%; Luxembourg 77%, Netherlands 68%, Portugal 58%; Spain 82%, Sweden 58%; UK 67% plus Norway, Switzerland and Iceland 0%.

Table 6 sets out changes in life satisfaction by country for the young aged 18-24 for the 18 countries that we have the full time-series available for.¹³ It shows declines over the period 2015-2024 in the majority of countries but *increases* in Italy, Ireland, Greece, Spain, Portugal and Austria as documented in **Figure 2**.

In **Table 7** we shift away from Eurobarometer to report changes in life satisfaction for high school students aged 15 as reported by Marquez et al. (2024). These both show declines in life satisfaction over the last decade starting prior to COVID. This is true in all countries including Italy and Spain in PISA (**Table 7a**) and Greece, Italy, Portugal and Spain in the HBSC survey (**Table 7b**). A major question to be explored further is why we observed declining life satisfaction among those age fifteen in these two surveys across similar years, but do not observe it using life satisfaction from the EB above, where we saw rising happiness. Below we argue that this is driven by what has happened in the youth labor market in the years since 2015.

Table 8 presents estimates of life satisfaction from the GWP 2018-2025. We include the age bands and, in each case, also report the results from the single year of age variable. For simplicity again we discuss the continuous age variable results. We find evidence of upward slopes, once again measured by the significance of the coefficient on the age variable and being positive ($T > 1.5$) for eight of the twelve from **Figure 1** - Denmark, Finland, Luxembourg, the Netherlands, Norway, Sweden and Turkey. The GWP results are broadly confirmatory. Consistently there are negative slopes in Greece, Italy, Spain and Portugal. So the GWP results are broadly consistent with those from Eurobarometer.

In **Table 9** we turn to the ESS. There is broad confirmation here that life satisfaction rises in age. In the first two columns of **Table 9** we find significant U-shapes in Austria, Belgium, France, Germany, Greece, Ireland, Portugal, Spain and the UK for the period 2014-2020. In the most recent sweep (2023/24), we see evidence of positive and significant age effects for eight of countries - Finland, Germany, Ireland, Netherlands, Norway, Sweden, Switzerland and UK. There are negative slopes again for France, Greece, Italy, and Portugal. We have no data for Denmark, Iceland or Turkey.

In **Table 10** we present life satisfaction estimates from GFS 2022. It is apparent again that life satisfaction rises with age in Germany, Sweden, Turkey and the UK but not in Spain.

In **Table 11** we show evidence from Global Minds that life satisfaction rises in age in each of the six countries asked the question. This is the first evidence for France we have found of an upward slope in life satisfaction in age.

4. Discussion

The evidence in Section Three is suggestive that across Western European the U-shaped association between age and life satisfaction disappeared. On the face of it this is no surprise since a similar development has been apparent elsewhere in the world. However, there are some important surprises in the evidence we provide in this paper. First, the timing of the change. It comes a little later than evidence from other studies, with much of the change taking place around the time of the COVID pandemic. Second, in most other studies the U-shape has been replaced

¹³ We only have data for 2021-2023 for Norway and Switzerland, 2021 and 2022 for Iceland.

by a roughly monotonic increase in wellbeing with age, due to a collapse in young people's wellbeing relative to older people. Here, by contrast, there is evidence for a subset of countries, that the wellbeing of the young has been *rising*. This is the case in Eurobarometer for Italy, Greece, Spain, Portugal, Cyprus and Austria (Table 6). Furthermore, in the period since COVID, regression analyses of Eurobarometer data indicate that life satisfaction has been *highest* among young people. If one examines Table 3 and Table 4 using Eurobarometer, this is the case in France, Italy, Greece, Spain, Cyprus and Portugal (for both CAWI and CATI data). The evidence on the age pattern in life satisfaction is less clear in some countries because life satisfaction is highest among the young in the CAPI surveys but not with CATI (these countries are Belgium, Germany, Austria, Malta and Turkey). In a further seven countries (the Netherlands, Luxembourg, Denmark, Ireland, the UK, Finland and Sweden) life satisfaction is rising in age in both the CAPI and CATI surveys.

Across other surveys evidence on the age pattern in life satisfaction is mixed. Life satisfaction is clearly rising in age in all six countries in Global Minds, which is a web-based survey. Although results from the Gallup World Poll for 2018-2025 are mixed, life satisfaction – measured with Cantril's Ladder – is highest among the young in the southern European countries (Italy, Greece, Spain, Portugal and Cyprus) and France, supporting the Eurobarometer results.

We can discount access to the internet as being an important discriminator in terms of what has happened to young people's life satisfaction across Western European countries. By 2010, according to United Nations data, access was high in all countries, and over 95% in Austria, Belgium, Denmark, Finland, France, Germany, Iceland, Luxembourg, Malta, Netherlands, Norway, Spain, Switzerland and the UK. Rates were lower in Cyprus (92%), Greece (88%), Ireland (90%), Portugal (91%) but lowest in Italy (85%) and Turkey (66%). By 2020 all countries had rates close to 100%.

Change in the labor market fortunes of the young is one potential reason for the fact that life satisfaction seems to have risen recently among the young relative to the old in Italy, Cyprus, France, Greece, Spain and Portugal. In these countries youth unemployment rates rose dramatically in the years after the Great Recession but have fallen rapidly in recent times.

Figure 3 illustrates this for six countries – France, Greece, Ireland, Italy, Spain, Portugal – where unemployment rates around 2015 peaked at over 30% and in the case of Greece and Spain at over 50%. But notably in the years after that, rates declined rapidly. Table 12 shows changes in youth unemployment rates for those aged 15-24 between 2015 and 2024 and calculates the ratio between the rate in 2024 and the rate in 2015. Appendix 2 reports youth unemployment rates for ages 18-24 obtained from the European Commission: we simply average monthly rates to get annual rates. In the case of Greece rates fell from 50.4% to 22.3% giving a ratio of .44. This can be compared to a ratio of .92 for Denmark, .90 for Switzerland and 1.22 for Sweden. Peak youth unemployment rates in earlier years were well below those in 2015.

In Table 13 we report six life satisfaction equations for Eurobarometer respondents aged 15-24. Columns 1 and 2 are for all countries. Columns 3 and 4 are for the group of thirteen countries with upward sloping age-life satisfaction profiles (Group 1) and columns 5 and 6 are for the group of eight countries without them. On each occasion we run estimates for the period before 2012 and

the period from 2012 onwards. We include the youth ratio as defined above, gender, year and country dummies. We cluster the standard errors at the country*year level.

In the first two columns for all 21 countries this youth unemployment ratio variable is negative and statistically significant in both the early and late periods. The implication is that the lower the ratio between the current youth rate, and the high point in 2015, the higher is the young person's life satisfaction.

For Group 1 countries the youth ratio is insignificantly different from zero in both periods. By contrast, for Group 2 countries in southern Europe it is significantly negative in both periods. The youth in these countries saw a rise in life satisfaction as the youth unemployment rate dropped rapidly over the years from 2015.

Labor market prospects for the young have improved more generally in these southern European countries. This is apparent from [Table 14](#) which shows the proportion of young people who are neither in employment, education, or training (NEET). This has dropped sharply in these countries.

A major part of the story seems to be the improving labor markets in these South European countries in the years since 2015 or so. These countries were hit especially hard by the financial market shock in the years from 2008 as can be seen from [Table 15](#) which shows GDP growth for the periods before and after the Great Recession. We know that marginal workers do worst in slumps and best in recessions, that seems to also be true of (peripheral) countries. The big story here is that the life satisfaction of the young rose between 2015 and 2024, as the youth unemployment rate fell from its peak reached in 2015. Young people are the last in and the first out, and their unemployment rate is more cyclically volatile than youth rates (Blanchflower, 1981). As Freeman and Wise (1982) noted “*youth employment is highly sensitive to cyclical movements in the economy*” (p.8). It seems the rise in life satisfaction of the young may reflect the absolute and relative improvement of these economies and labor markets in the most recent period.

Our main finding though is that the U-shape in life satisfaction by age, present for so long, has now vanished in 12 northern European countries - Belgium, Denmark, Finland, Germany, Iceland, Ireland, Luxembourg, the Netherlands, Norway, Sweden, Switzerland and the - UK plus Turkey. Life satisfaction in these countries now *rises* in age.

Negative/positive means coefficient has absolute $t \geq 1.5$. Column 2 reports results from the inclusion, a 15-24 dummy Column 3 reports results from including age and its square as controls. If one or both are insignificant, we report Not Significant (NS), and if age is significantly negative and age squared is significantly positive we solve for a minimum which is reported in column 3. *=U-shape.

b) Sign on age variable

Q1. “The following question asks how satisfied you feel about your life, on a scale from “0” to “10”. Zero means you feel ‘not at all satisfied’ and “10” means ‘completely satisfied’. Overall, how satisfied are you with your life as a whole these days?”.

Table 7b. HBSC life satisfaction Age 15

	2017/18	2021/22	2022-2017
